

CONTROL AND ITERATION 1

DATA C88C

August 31, 2022

1 Control

Control structures direct the flow of logic in a program. For example, conditionals (`if-elif-else`) allow a program to skip sections of code, while iteration (`while`), allows a program to repeat a section.

1.1 If statements

Conditional statements let programs execute different lines of code depending on certain conditions. Let's review the `if-elif-else` syntax:

```
if <conditional expression>:
    <suite of statements>
elif <conditional expression>:
    <suite of statements>
else:
    <suite of statements>
```

Recall the following points:

- The `else` and `elif` clauses are optional, and you can have any number of `elif` clause.
- A **conditional expression** is a expression that evaluates to either a true value (`True`, a non-zero integer, etc.) or a false value (`False`, `0`, `None`, etc.).
- Only the **suite** that is indented under the first `if/elif` that has a **conditional expression** that evaluates to `True` will be executed.
- If none of the **conditional expressions** are `True`, then the `else` suite is executed. There can only be one `else` clause in a conditional statement!

1.2 Boolean Operators

Python also includes the **boolean operators** `and`, `or`, and `not`. These operators are used to combine and manipulate boolean values.

- `not` returns the opposite truth value of the following expression.
- `and` short-circuits at the first `False` value and returns it. If all values evaluate to `True`, the last value is returned.
- `or` short-circuits at the first `True` value and returns it. If all values evaluate to `False`, the last value is returned.

```
>>> not None
True
>>> not True
False
>>> -1 and 0 and 1
0
>>> False or 9999 or 1/0
9999
```

1.3 Questions

1. Determine what the Python interpreter will output given the following lines of code.

```
>>> from operator import add, mul
>>> mul(add(5, 6), 8)
```

Solution: 88

```
>>> print('x')
```

Solution: x

```
>>> y = print('x')
```

Solution: x

```
>>> print(y)
```

Solution: None

```
>>> print(add(4, 2), print('a'))
```

Solution: a 6 None

```
def foo(x):  
    print(x)  
    return x + 1
```

```
def bar(y, x):  
    print(x - y)
```

```
>>> foo(3)
```

Solution:

3
4

```
>>> bar(3)
```

Solution: Error

```
>>> bar(6, 1)
```

Solution: -5

```
>>> bar(foo(10), 11)
```

Solution:

10
0

2. Tommy will only wear a jacket outside if it is below 60 degrees or it is raining.

Write a function that takes in the current temperature and a boolean value telling if it is raining and returns `True` if Tommy will wear a jacket and `False` otherwise.

First, try solving this problem using an `if` statement.

```
def wears_jacket_with_if(temp, raining):  
    """  
    >>> wears_jacket_with_if(90, False)  
    False  
    >>> wears_jacket_with_if(40, False)  
    True  
    >>> wears_jacket_with_if(100, True)  
    True  
    """
```

Solution:

```
if temp < 60 or raining:  
    return True  
else:  
    return False
```

Note that we'll either return `True` or `False` based on a single condition, whose truthiness value will also be either `True` or `False`. Knowing this, try to write this function using a single line.

```
def wears_jacket(temp, raining):
```

Solution:

```
return temp < 60 or raining
```

3. To handle discussion section overflow, Matt and other TAs may direct students to a more empty section that is happening at the same time.

Write a function that takes in the number of students in two sections and prints out what to do if either section exceeds 30 students.

Hint: You can do `str(<number>)+ <string>` to concatenate a number and a string

```
def handle_overflow(s1, s2):  
    """  
    >>> handle_overflow(27, 15)  
    No overflow  
    >>> handle_overflow(35, 29)  
    Move to Section 2: 1  
    >>> handle_overflow(20, 32)  
    Move to Section 1: 10  
    >>> handle_overflow(35, 30)  
    No space left in either section  
    """
```

Solution:

```
if s1 <= 30 and s2 <= 30:  
    print("No overflow")  
elif s2 > 30 and s1 < 30:  
    print("Move to Section 1:" + str(30 - s1))  
elif s1 > 30 and s2 < 30:  
    print("Move to Section 2:" + str(30 - s2))  
else:  
    print("No space left in either section")
```

4. Write a function that returns `True` if a positive integer n is a prime number and `False` otherwise.

A prime number n is a number that is not divisible by any numbers other than 1 and n itself. For example, 13 is prime, since it is only divisible by 1 and 13, but 14 is not, since it is divisible by 1, 2, 7, and 14.

Hint: use the `%` operator: `x % y` returns the remainder of `x` when divided by `y`.

```
def is_prime(n):  
    """  
    >>> is_prime(10)  
    False  
    >>> is_prime(7)  
    True  
    """
```

Solution:

```
if n == 1:  
    return False  
k = 2  
while k < n:  
    if n % k == 0:  
        return False  
    k += 1  
return True
```

Alternatively, the while loop's conditional expression could ensure that k is less than or equal to the square root of n .
